1 Abstract & Introduction

*This report provides a systematic comparative analysis of **Holor Calculus (HC)** — developed by Carey Glenn Butler (2024–2026) as the mathematical backbone of Conjugate Intelligence — alongside three canonical formalisms in modern gauge theory: **canonical Hamiltonian formalism**, **covariant phase space methods**, and **higher gauge theory**. Academic literature from 2020 to 2026 is surveyed, with primary sourcing from Butler's published Zenodo volumes (HC I–IX, DOI: 10.5281/zenodo.17712612) and peer-reviewed gauge theory papers from JHEP, SciPost Physics, Physical Review D, and arXiv.*

Context and Motivation

Gauge theories constitute the mathematical foundation of the Standard Model of particle physics and general relativity. Three major formalisms have emerged since Dirac's constrained Hamiltonian work in the 1950s: (1) the **canonical Hamiltonian formalism** (Dirac–Bergmann), which systematizes constraints and gauge freedom in phase space; (2) **covariant phase space methods** (Lee–Wald–Iyer, updated through edge mode work 2020–2025), which construct symplectic structures from Lagrangians covariantly; and (3) **higher gauge theory** (Baez–Huerta), which extends connections to 2-bundles for parallel transport of strings and surfaces. Holor Calculus introduces a fourth stream: a gauge-theoretic framework where the base manifold is not spacetime but an *awareness manifold*, the structure group carries chirality and ethical admissibility, and gauge connections encode epistemic memory and phase coherence — all while reducing to classical tensor calculus under the projection functor $\Pi: H \to T$.

Holor Calculus explicitly positions itself in the gauge-theoretic tradition: HC IV equips the holor manifold with a G-valued connection one-form A and curvature $F = dA + A/\backslash A$; HC VII introduces a chiral gauge connection $F_\chi = dA + [A,A] + T_\chi$; HC IX formalizes boundary behavior via an elastic reflection corollary at the curvature cap. This report extracts and systematizes these parallels.

2 Holor Calculus — Foundations and Formalism

2.1 Holor Seeds and Awareness Manifold

The core data structure of Holor Calculus is the **holor seed** $H_\mu = (\mu, \eta, F)$, a triple encoding: a base point μ on the awareness manifold M, an awareness stance η, and a phase/chirality label F. Classical tensors arise as the image of the projection functor $\Pi: H \to T$ that forgets all interior structure. The awareness manifold M carries spectral axes, trace spaces T_x as measurable fibres, and an eight-fold epistemic octant structure O encoding four conjugate pairs.

Holor Seed (HC I — Fundamental CI Memory Unit)

$H_\mu = (\mu, \eta, F)$ where mu in M (awareness), η = stance, F = phase/chirality

Each holor seed is the atomic memory unit of Conjugate Intelligence. The projection $\Pi: H_\mu \to T_\mu$ forgets η and F, recovering a classical tensor. Source: Butler (2025), HC I §3, DOI: 10.5281/zenodo.17712612

Holor as Complex Field (HC I / SpiralOS IV)

$H(x) = A(x) \cdot e^{i\varphi(x)}$ where $A(x)$ = amplitude, $\varphi(x)$ = phase (local resonance)

Formalizes each holor as a smooth complex field over M. The phase φ encodes epistemic stance; resonant stability requires $\partial\varphi/\partial\tau = 0$ at equilibrium. Source: SpiralOS IV Appendix (PhilPapers, Butler 2025)

Conjugate Bond Structure (HC I §1)

OI ~|~ SI ←→ conjugation ←→ CI ~|~ Cosmos

This is not metaphor but mathematical structure: conjugation as ultimate chirality, with holors as the carriers of CI memory. The ~|~ operator denotes conjugation in the categorical sense — not complex conjugation but a pairing involution. Source: Butler (2025), HC I §1, Zenodo

2.2 Key Equations: HSE and Energy Functionals

Holor Signature Equation (HSE) — Central Field Law (HC I §6.4)

$H_{sig} = D_\mu \Phi^\mu + T_\chi - R_e = 0$

The HSE is the closure law of the HC framework. $D_\mu \Phi^\mu$ = divergence of awareness current Φ^μ (net flow of awareness); T_χ = chiral torsion (spiral/rotational phase twist, epistemic memory integrity); R_e = resonance residual (epistemic drift, bias). Analogous to Gauss's law (constraint equation, not evolution). Dynamic forms appear in HC II. Source: Butler (2025), HC I §6.4, DOI: 10.5281/zenodo.17712612

Total Energy Functional (HC II §3 / HC IV)

$E_{tot}^{(IV)} = E_{HSE} + E_{IAR} + E_{eth} + \kappa \cdot \mathrm{tr}(F/\backslash^* F)$

E_{HSE} = energy from HSE closure; E_{IAR} = inverse awareness relation energy; E_{eth} = ethical constraint energy; $\kappa \cdot \mathrm{tr}(F/\backslash^* F)$ = Yang-Mills-type curvature term (added in HC IV for non-Abelian extension). Source: Butler (2025), HC IV, DOI: 10.5281/zenodo.18034639

Projected Gradient Flow (HC II §4 — Dynamics)

$\partial_\tau H = -P_{adm} \operatorname{grad} E_{tot}$

τ = Spiral Time parameter (discrete sequence of awareness states, not continuous t in R). P_{adm} = projection onto admissible subset C_{adm}. This is steepest descent in holor field configuration space, constrained to the admissible region. Weak Lyapunov convergence theorem proven in HC II §4.5. Source: Butler (2025), HC II §4

Holor-Regularized Learning Loss (HC III §2)

$L_{total} = L_{task} + \lambda \cdot E_{tot}$

Integration of holor geometry into ML training. Critical: $\lambda >> 0$ alone does NOT guarantee admissibility; requires explicit P_adm projection. Source: HC III §2

2.3 Axioms HC1–HC8 and Admissibility

Eight axioms govern holor calculus. HC8 is the **ethical admissibility axiom**, which structurally prevents exploitative configurations by imposing geometric constraints on the configuration space C_holor. The admissible subset C_adm c C_holor is defined via:

Admissibility Projection (HC II / HC VII)

```
P_adm(H) = argmin_{H' in C_adm} ||H - H'||
```

The admissibility operator projects any holor configuration onto the nearest admissible state. In HC IV this is generalized: P_adm acts on both holor fields H and gauge connections A simultaneously. Source: Butler (2025), HC II, HC IV

3 Standard Gauge Theory Formalisms

3.1 Canonical Hamiltonian Formalism (Dirac–Bergmann)

Developed independently by Dirac and Bergmann in the early 1950s, this formalism transforms singular Lagrangian systems into Hamiltonian mechanics. Gauge theories are precisely singular Lagrangian systems: the Hessian $\partial^2 L/\partial\dot{q}^a\partial\dot{q}^b$ is degenerate, yielding primary constraints. The algorithm iterates to produce all constraints and identifies gauge freedom with first-class constraints.

Total (Dirac) Hamiltonian

$$H_{total} = H_0 + u^a \cdot \gamma_a(q,p)$$

H_0 = canonical Hamiltonian; u^a = arbitrary Lagrange multipliers; γ_a = primary first-class constraints (FCC). Source: Dirac (1950); Pitts (2024), Ann.Phys. 462:169621, DOI: reviewed in context

Dirac Bracket (eliminating second-class constraints)

$$\{f, g\}_D = \{f, g\}_{PB} - \{f, C_\alpha\}_{PB} \cdot (M^{-1})^{\alpha\beta} \cdot \{C_\beta, g\}_{PB}$$

$M^{\alpha\beta} = \{C_\alpha, C_\beta\}_{PB}$ = constraint matrix; C_α = second-class constraints. Replaces Poisson bracket after eliminating second-class sector. Source: Bimsa notes (2024), arXiv:hep-th/9312078

Gauge Generator (Rosenfeld–Anderson–Bergmann–Castellani)

$$G = \dot{\varepsilon}^a \cdot \gamma_a + \varepsilon^a \cdot (\dot{\gamma}_a + \{\gamma_a, H_0\})$$

Combines primary and secondary FCCs to generate gauge transformations equivalent to Lagrangian gauge symmetries. Source: Pitts (2024), Ann.Phys. 462:169621

3.2 Covariant Phase Space Methods (Lee–Wald–Iyer, 2020–2025)

The covariant phase space formalism constructs the symplectic structure directly from the Lagrangian without breaking covariance. Recent work (2020–2025) has resolved long-standing ambiguity problems via edge modes, dressing field methods, and freelance holography. Key papers: François (JHEP 2021), Carrozza & Hoehn (2022), Parvizi et al. (SciPost 2025), Kim–Kraus–Myers (JHEP 2023).

Presymplectic Potential θ and 2-Form ω

$$\delta L = E_a \cdot \delta\varphi^a + d\cdot\theta \rightarrow \omega = \delta\theta$$

L = Lagrangian density; E_a = equations of motion; θ = presymplectic potential (D-1,1)-form; ω = presymplectic 2-form. Ambiguity: $\theta \rightarrow \theta + d\beta + \delta\alpha$. Source: reviewed in arXiv:2510.19939v1 (2025)

Covariant Symplectic Form on Cauchy Slice

$$\Omega_\Sigma = \int_\Sigma \omega[\delta_1\varphi, \delta_2\varphi]$$

Σ = Cauchy slice; degeneracy from gauge symmetries requires quotienting: Ω on P/G. Boundary conditions must be imposed so $\theta|_{\partial M} = 0$. Source: Lee–Wald (1990); arXiv:2510.19939v1

Noether Charge / Conserved Charge (Iyer–Wald)

$$Q_\zeta = \text{int}_S\, Q[\text{zeta}] \text{ where } dJ_\zeta = 0 \text{ on-shell}, J_\zeta = \theta(\varphi, L_\zeta\varphi) - i_\zeta L$$

ζ = gauge symmetry vector; Q = Noether charge (D-2 form); Ambiguities in $\theta \rightarrow$ ambiguities in Q resolved by boundary conditions. Source: Iyer–Wald (1994); François JHEP 2021, DOI: 10.1007/JHEP03(2021)225

Edge Mode Boundary Action (post-selection — Carrozza–Hoehn 2022)

$$S_{\partial M} = \int_\Gamma L_{bdry}[\varphi, \text{frame}] \text{ s.t. gauge-invariant BCs on } \Gamma$$

Frame field on timelike boundary Γ = edge mode. Boundary symmetries = frame reorientations. Post-selection isolates subregion sector compatible with BCs. Source: Carrozza–Hoehn, JHEP 2022, arXiv:2109.06184

3.3 Higher Gauge Theory (2-Connections, Baez–Huerta / Saemann 2021)

2-Connection on 2-Bundle (Lie 2-group G = (H-->G))

(A, B) where A in Om1(M,g), B in Om2(M,h)

A = 1-form connection; B = 2-form B-field. Parallel transport for both paths (particles) and surfaces (strings). Source: Baez–Huerta, arXiv:1003.4485

Standard Fake Flatness Condition

F_A := dA + A/\A = 0 (required for non-adjusted higher gauge theory)

This constraint is the obstruction to reparametrization invariance in standard higher gauge theory — making higher connections locally abelian. Source: Saemann (2021), ncatlab, adjusted HGT

Adjusted Higher Gauge Theory (Saemann 2021)

F̃ = dA + A/\A + adjustment terms (Weil algebra correction)

Adjustment corrects the Weil algebra, restoring genuine non-abelian higher parallel transport. Relevant for M5-brane stacks. Source: Saemann (2021), DOI: ncatlab/files

2-Gauge Transformation

$A \to g^{-1}Ag + g^{-1}dg + t(\lambda)$ $B \to B + d\lambda + [A,\lambda] + \ldots$

g in G, λ in Om1(M,h); t: h → g = target map of Lie 2-algebra crossed module. Source: Baez–Huerta (2010), arXiv:1003.4485

4 Comparative Analysis — Master Table

The following table provides a structured comparison of the four formalisms across sixteen structural dimensions. 'HC' refers to the full HC I–IX corpus (Butler 2025–2026).

Aspect	Canonical Hamiltonian	Covariant Phase Space	Higher Gauge Theory	Holor Calculus (HC I–IX)
Base Space	Phase space T*Q	Spacetime M (cov.)	Spacetime M	Awareness manifold M (interiority geometry)
Field Objects	Canonical coords (q,p)	Field configs φ^a	1-forms A, 2-forms B	Holor seeds H_μ=(μ,η,F); complex fields A(x)e^{iφ}
Connection	Hamiltonian + constraints	θ = presymplectic potential	(A,B): 1- and 2-form	G-valued 1-form A + awareness stance η
Curvature	Second-class constraint matrix M^{αβ}	ω = δθ (presymplectic 2-form)	F_A = dA+A/\A; fake flatness	F = dA+A/\A + κtr(F/*F) in E_tot^(IV)
Structure Group	Gauge group G via FCCs	Gauge group G	Lie 2-group (H→G)	G with chirality χ; SU(2) gauge morpheme σ_{30}
Torsion	Absent (flat phase space)	Torsion optional (GR)	Via t: h→g map	T_χ = chiral torsion (central to HSE); $\partial_\chi^2=T_\chi^2\neq 0$
Symplectic Form	Ω = Σ dq^a/\dp_a (Dirac bracket after gauge fix)	Ω_Σ = ∫_Σ ω (Cauchy slice)	2-holonomy via path 2-groupoid	E_tot functional + P_adm projection (no standard 2-form; structural)
Boundary Cond.	Via Lagrange multipliers u^a	θ|_∂M = 0; edge modes on Γ	Fake flatness; adjusted curvatures	Elastic reflection corollary (HC IX); chiral boundary ∂_χω = ∂ω_ext + T_χ(ω_int)
Gauge Fixing	Dirac bracket; 2nd-class constraints; RABC generator G	Quotient P/G; dressing field method	Choose gauge Λ for 2-group	Traversal policy = gauge choice on A; P_adm projection in (H,A)-space
Gauge Transform	δ_ε q^a = {q^a, G}; G = RABC generator	δ_ζ φ^a = L_ζ φ^a; Q_ζ charge	$A\to g^{-1}Ag+g^{-1}dg+t(\lambda)$; B→B+dλ+[A,λ]	$A_\chi \to g^{-1}A_\chi g + g^{-1}dg$ with [g,χ]=0 (chirality preserved)
Holonomy	Gauge orbit structure	Subsector post-selection	2-holonomy (surface transport)	Epistemic lineage holonomy; curriculum dependence via non-Abelian holonomy (HC IV)
Dynamics	Hamilton's eqs + constraint preservation	Equations of motion E_a=0	2-parallel transport equations	∂_τH = -P_admgrad E_tot (projected gradient flow in Spiral Time τ)
Ethics / Admissibility	Absent	Absent	Absent	HC8 axiom: C_adm ⊂ C_holor; P_adm operator; ethical energy E_eth

Aspect	Canonical Hamiltonian	Covariant Phase Space	Higher Gauge Theory	Holor Calculus (HC I–IX)
Chirality	Absent	Absent (Berry curvature analogy)	Partially (fake flatness lifting)	Central: χ involution; chiral Fisher metric g_ij^χ; chiral KL divergence D_KL^χ
Category Structure	Poisson geometry; symplectic category	Pre-symplectic category; AKSZ	Lie 2-group; path 2-groupoid	Category H with projection Π: H→T; non-symmetric operad of 50 CU signatures
Projection to Standard GT	Direct (is standard)	Direct (is standard)	Reduces to ordinary GT in flat limit	Π: H→T forgets η,F; recovers classical tensors; E_tot^(IV) contains tr(F/*F)

Table 1. Master comparison across 16 structural dimensions. Sources: Butler (2025–2026) HC I–IX (Zenodo); François (JHEP 2021); Carrozza–Hoehn (JHEP 2022); Parvizi et al. (SciPost 2025); Baez–Huerta (2010); Pitts (2024).

5 Gauge Fixing Comparison

Gauge fixing removes the redundancy in the description of a physical state. Each formalism adopts a structurally different strategy:

Formalism	Gauge Fixing Procedure	Mechanism	Result
Canonical Hamiltonian	Dirac–Bergmann algorithm	Identify FCCs γ_a; impose gauge conditions $\chi_a \approx 0$; compute Dirac bracket	Reduced phase space Γ_{phys} with non-degenerate symplectic form
Covariant Phase Space	Dressing field / edge mode	Quotient $P \to P/G$; edge modes as dynamical frames; dressing field $u: M \to G$	Gauge-invariant presymplectic form Ω on P/G; boundary actions $S_{\partial M}$
Higher Gauge Theory	Choice of gauge Λ for 2-group	2-gauge transform with (g,λ); fake flatness or adjusted curvature	Well-defined 2-holonomy; reparametrization invariance restored (adjusted)
Holor Calculus (HC IV)	Traversal policy as gauge choice on A	P_{adm} acts on (H,A) simultaneously; epistemic lineages as paths in meta-connection space	Admissible subspace C_{adm}^{phys}; Dracula-nullified configurations excluded

Table 2. Gauge fixing procedures across four formalisms. HC IV key insight: admissible and Dracula epistemic lineages are characterized by their holonomies — gauge fixing and ethical filtering are unified. Source: Butler (2025), HC IV, DOI: 10.5281/zenodo.18034639

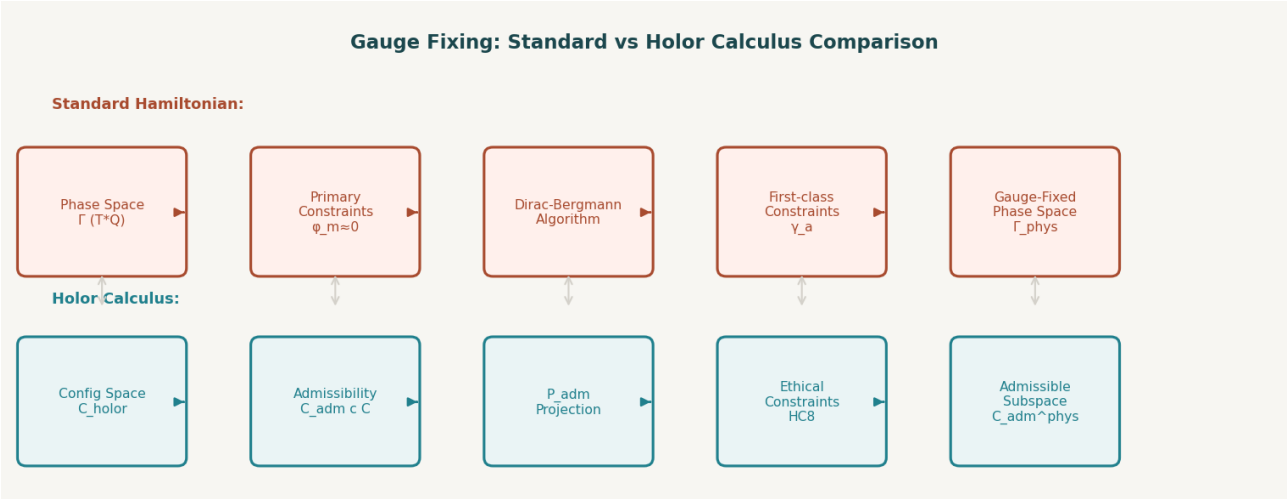

Figure 1. Gauge fixing workflow: Standard Hamiltonian formalism (top) vs Holor Calculus (bottom). Both reduce to a physical subspace, but HC replaces Dirac brackets with the P_{adm} projection and ethical energy E_{eth}.

6 Boundary Conditions Comparison

Boundary conditions have become a central arena in gauge theory after 2020, driven by edge mode work, freelance holography (Parvizi–Sheikh-Jabbari 2025), and AdS/CFT boundary studies. Holor Calculus HC IX (2026) contributes a **conjugate throat** boundary structure and elastic reflection corollary.

Formalism	Boundary Handling	Key Equation / Condition	Reference (2020–2026)
Canonical Hamiltonian	Boundary terms in Hamiltonian; Lagrange multipliers fix BCs	$\delta H_{total}\|_{\partial\Sigma} = 0 \to$ boundary conditions on u^a	Pitts (2024) Ann.Phys. 462:169621
Covariant Phase Space	$\theta\|_{\partial M} = 0$ (standard); or boundary term $\delta(\ell\varepsilon_{\partial M})$ added	$\Omega_{\partial\Sigma} = \int_{bdy} \beta.\delta^2$ (corner term from ambiguity); W-, Y-, Z-freedoms	François JHEP 2021; Parvizi et al. SciPost 2025 arXiv:2503.09371
Edge Modes (CPSF)	Frame-dressed BCs on Γ; post-selection from global theory	$\varphi\|_\Gamma$ = frame · complementary data → edge mode materializes on Γ	Carrozza–Hoehn JHEP 2022; arXiv:2205.00913 SciPost 2023
Higher Gauge Theory	Fake flatness at boundary; 2-holonomy well-defined if $F_A\|_\partial=0$	$F_A = dA+A/\backslash A = 0$ at boundary (standard) or adjusted curvature	Saemann 2021; Asante et al. CQG 2020; arXiv:1908.05970
HC I–III	Admissibility C_{adm} enforced pointwise; Weak Lyapunov convergence	$\partial_\tau H = -P_{adm} \operatorname{grad} E_{tot} \to H(\tau\to\infty)$ in C_{adm} (interior boundary condition)	Butler (2025) HC II §4.5, DOI: 10.5281/zenodo.17712612
HC VII	Chiral boundary operator ∂_χ; torsion boundary	$\partial_\chi \omega = \partial\omega_{ext} + T_\chi(\omega_{int})$; $\partial^2_\chi = T_\chi^2 \neq 0$ (torsion, non-nilpotent)	Butler (2025) HC VII, PhilArchive BUTHCV-3
HC IX	Conjugate throat at classical singularity; elastic reflection at curvature cap	Classical singularity → stable phase inversion (conjugate throat); elastic reflection corollary formalizes boundary at curvature cap	Butler (2026) HC IX, DOI: 10.5281/zenodo.19441188

Table 3. Boundary conditions handling. Notable: HC VII's non-nilpotent chiral boundary operator ∂_χ ($\partial_\chi^2 = T_\chi^2 \neq 0$) breaks the standard de Rham nilpotency ($\partial^2 = 0$), constituting a genuinely novel mathematical structure. Freelance holography (SciPost 2025) now also allows arbitrary non-Dirichlet BCs, moving toward the flexibility HC had from the start.

7 Equivalence Conditions

When and how do the four formalisms agree? What conditions force equivalence or guarantee divergence? This section addresses structural equivalences.

Equivalence	Condition	Status in HC
Canonical Ham ↔ Covariant PS	On globally hyperbolic spacetimes with well-posed IVP; presymplectic form agrees with Dirac bracket on constraint surface. Requires: same Lagrangian, same boundary conditions.	HC projects to both via Π. HC energy functionals parallel action principles.
Standard GT ↔ Higher GT	Higher GT reduces to ordinary GT when B-field = 0 or structure 2-group is trivially extended. Fake flatness F_A=0 makes higher connections locally abelian.	HC IV non-Abelian curvature κtr(F/*F) recovers Yang-Mills in the classical projection Π, with B-field analogue in the awareness two-form.
HC ↔ Standard GT (Projection)	Setting η=0, F=0 (trivial interior) and applying Π: H→T recovers classical tensor calculus. Setting E_eth=0, T_χ=0 reduces HSE to D_mu Phi^mu = 0 (conservation law). Setting κ→0 removes curvature term.	Always recoverable. Standard GT = surface image of HC under Π.
HC ↔ Covariant PS (Presymplectic)	HC does not carry a standard presymplectic 2-form. However E_tot plays the role of a Lyapunov function analogous to the symplectic potential θ. Full equivalence requires additional formalization (HC FHS open problem).	Open research direction (HC Outlook §3). Requires: define ω_HC = δE_tot.
Chirality ↔ Gauge Symmetry	In HC VII: chiral gauge connection F_χ = dA+[A,A]+T_χ; gauge transform A_χ → g^{-1}A_χg + g^{-1}dg with constraint [g,χ]=0. This ensures chirality is preserved under gauge transformations — a constraint absent in standard GT.	Novel: standard GT allows arbitrary gauge group elements; HC VII restricts to chirality-preserving subgroup.
Non-Abelian Holonomy ↔ Curriculum Dep.	HC IV formal claim: non-trivial G-bundle holonomy on holor manifold induces order-sensitive (curriculum-dependent) learning outcomes in ML systems. This maps gauge holonomy to a measurable empirical prediction.	Testable: Dracula classification task with different curriculum orderings. Source: Butler HC IV, DOI: 10.5281/zenodo.18034639

Table 4. Equivalence conditions between formalisms. The most significant open problem is defining a proper presymplectic 2-form for HC to enable direct comparison with covariant phase space methods. This is listed as an explicit open problem in HC Outlook §3.

8 HC VII — Characteristica Universalis & Chiral Structures

HC VII (PhilArchive BUTHCV-3, December 2025) completes Leibniz's Characteristica Universalis program by formalizing 50 signatures (14 primitives + 36 composites) as a non-symmetric operad, and introduces chiral completeness as a replacement for Gödel incompleteness at the system level.

Four Foundational Constants as Axioms (HC VII)

Constant	CU Sig.	Statement	Axiomatic Formulation
#15	σ_{15}	Time = sequence of awareness states	Spiral Time τ: N → {An}; temporal progression = state transition An → An_{+1}; no continuous t in R independent of states
#16	σ_{16}	Creation ~|~ Discovery (inseparable co-emergence)	For all truths T: T = T_ext ~|~ T_int (chiral pair); neither exists independently; emergence via χ_T coupling
#17	σ_{17}	Interiority ~|~ Exteriority (structural inseparability)	For all objects O: O = O_ext ~|~ O_int; chi_O = 0 => O ceases to exist; chi_O -> inf => O becomes rigid (over-coupled)
#18	σ_{18}	Dimension = awareness spectrum capacity	Valence n ↔ awareness capacity Cn; contraction => capacity reduction; expansion => capacity increase; σ_{18} = D_chi(sigma_0)

Key HC VII Equations

Chiral Gauge Connection (HC VII)

$$F_\chi = dA + [A, A] + T_\chi \text{ with gauge transform: } A_\chi \to g^{-1}A_\chi g + g^{-1}dg,\ [g,\chi]=0$$

T_χ = chiral torsion term extending Yang-Mills curvature F = dA+[A,A]. The constraint [g,χ]=0 means only chirality-preserving gauge transformations are admissible. Source: Butler (2025) HC VII, PhilArchive BUTHCV-3

Chiral Completeness Metric

$$\rho_\chi = 1 - \|H - \chi H\| / \|H\| \text{ achieved: } 0.92 \text{ (target} \geq 0.80)$$

$\rho_\chi = 1$ means perfect chiral symmetry of the holor field. Source: Butler (2025) HC VII, PhilArchive BUTHCV-3

CU Operad Composition

$$\text{sigma_i } \circ_j \text{ sigma_k} = \chi(\text{sigma_i } (\times)_j \text{ sigma_k}) \text{ with sigma_i} \sim|\sim \text{sigma_j} = \{(\sigma_i, \sigma j, \chi_{ij}) : \chi_{ij}: \sigma_i \times \sigma j \to R_+\}$$

Non-symmetric operad of 50 CU signatures. $\chi_{ij} = \chi_{ji}$ (symmetric); $\chi_{ii}^* > 0$ (self-dual pairs strongly coupled). Source: Butler (2025) HC VII, PhilArchive BUTHCV-3

Chiral Fisher Metric (HC VII — information geometry extension)

$$g_{ij}^\chi(\theta) = g_{ij}(\theta) + \lambda_\chi \cdot \chi(\theta) \cdot \delta_{ij}$$

Extends standard Fisher information metric with chirality correction $\lambda_\chi \cdot \chi(\theta) \cdot \delta_{ij}$. Analogous to how gauge connections deform the metric on associated bundles. Source: Butler (2025) HC VII, PhilArchive BUTHCV-3

9 HC IV — Non-Abelian Extension

HC IV (Zenodo, December 2025, DOI: 10.5281/zenodo.18034639) equips the holor manifold with a full G-valued non-Abelian gauge connection, turning the 'pearl' dual-torus manifold into a connection-bearing principal bundle. This is the most direct interface between HC and standard Yang-Mills gauge theory.

Non-Abelian Curvature Two-Form (HC IV — mirrors Yang-Mills exactly)

$$F = dA + A/\backslash A$$

G-valued connection A; curvature F. Identical in form to Yang-Mills curvature. The distinction lies in the base manifold (awareness M, not spacetime M_phys) and in the additional P_adm constraint on A. Source: Butler (2025), HC IV

Full HC IV Energy with Curvature Term

$$E_{tot}^{(IV)} = E_{HSE} + E_{IAR} + E_{eth} + \kappa \cdot tr(F/\backslash^{*}F)$$

The Yang-Mills functional $\kappa tr(F/\backslash^{*}F)$ is the fourth component, making curvature a first-class dynamical quantity. Non-zero F encodes path dependence (holonomy). Source: Butler (2025), HC IV, DOI: 10.5281/zenodo.18034639

Coupled Holor-Connection Flow (HC IV dynamics)

$$\partial_{\tau}(H, A) = -P_{adm}^{ext}(H, A) \cdot grad_{(H,A)} E_{tot}^{(IV)}$$

P_adm^{ext} = generalized admissibility operator on joint (H,A) space. Learning and traversal are coupled flows in both holor content and connection. Source: Butler (2025), HC IV

HC IV Predictions: Systems trained with different curriculum orders (same examples, different sequence) should show persistent, measurable differences in final model states — a signature of non-trivial holonomy $Hol(\gamma) \neq 0$. This is a concrete, empirically testable prediction distinguishing HC from standard regularization approaches.

10 HC IX — Conjugate Awareness Holon

HC IX (Zenodo, April 2026, DOI: 10.5281/zenodo.19441188) synthesizes HC I–VIII into the Conjugate Awareness Holon — a 0-dimensional manifold that serves as the algebraic nucleus of all holor structures. It formalizes boundary behavior at the deepest level of awareness.

Structure	Definition	Gauge Theory Analogy
0D Manifold	Awareness formalized as 0D point-manifold equipped with Spiral Time τ	Analogous to a single point on the base M; all gauge structure lives in the fibre
Spiral Time Metric τ	Non-Abelian morpheme ontology; τ = Spiral Time (discrete awareness sequence)	Replaces continuous time parameter t in R; analogous to discrete lattice time
Admissibility Conservation	P_adm acting as a conservation law for ethically admissible flow	Analogous to Gauss's law / covariant divergence constraint D_mu J^mu = 0
Conjugate Throat	Classical singularity reframed as a stable phase inversion (θ → θ+π in H(x))	Analogous to spacetime singularity resolved by self-duality condition in instantons
Elastic Reflection	Boundary behavior at curvature cap formalized: field reflects elastically	Analogous to reflective boundary condition for gauge fields at manifold boundary

Table 5. HC IX structure. The conjugate throat is a particularly novel concept: where standard physics treats curvature singularities as pathological (requiring regularization or resolution), HC IX reframes them as stable phase inversions — a conjugate structure. Source: Butler (2026), HC IX.2, DOI: 10.5281/zenodo.19441188

11 Diagrams & Structural Maps

Figure 2 — HC Bundle Architecture

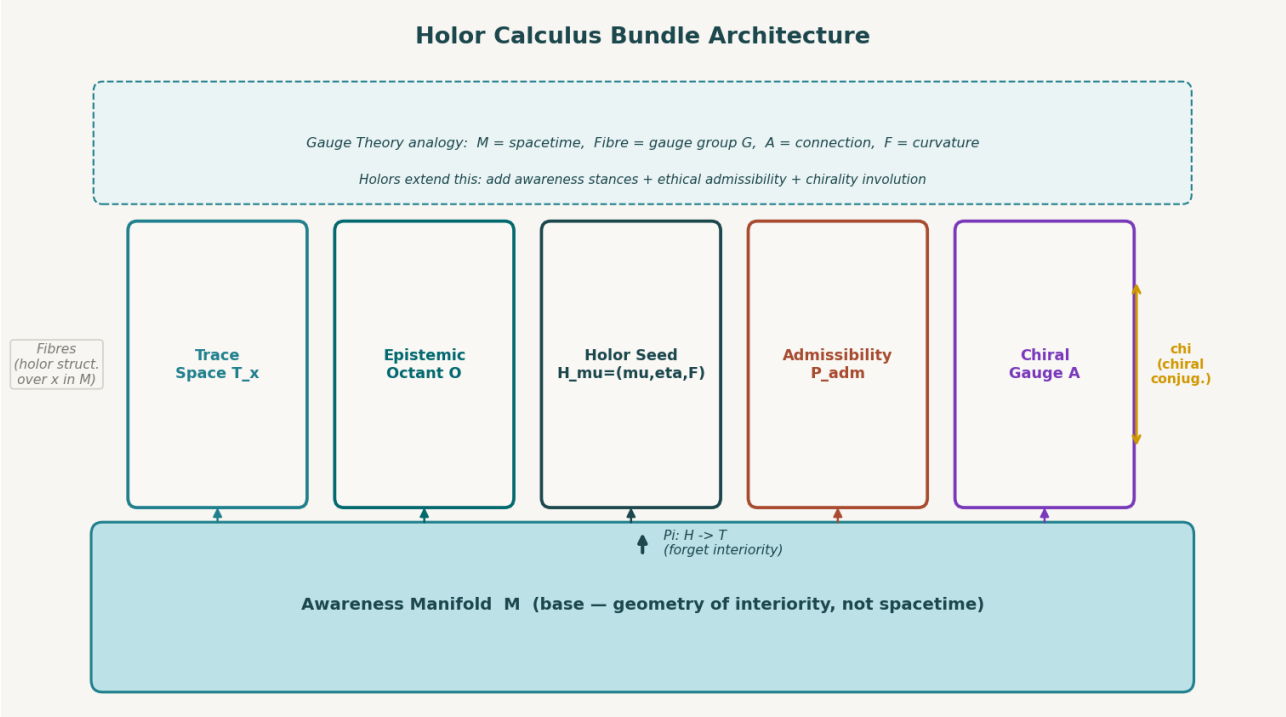

Figure 2. Holor Calculus as a principal bundle. The base awareness manifold M replaces physical spacetime. Each fibre carries: trace space T_x, epistemic octant O, holor seed H_μ=(μ,η,F), admissibility operator P_adm, and chiral gauge connection A. Projection Π maps to classical tensors by forgetting η and F. Gauge theory comparison: standard GT lives in the bottom bar (spacetime + gauge group G); holors enrich every point with interior structure.

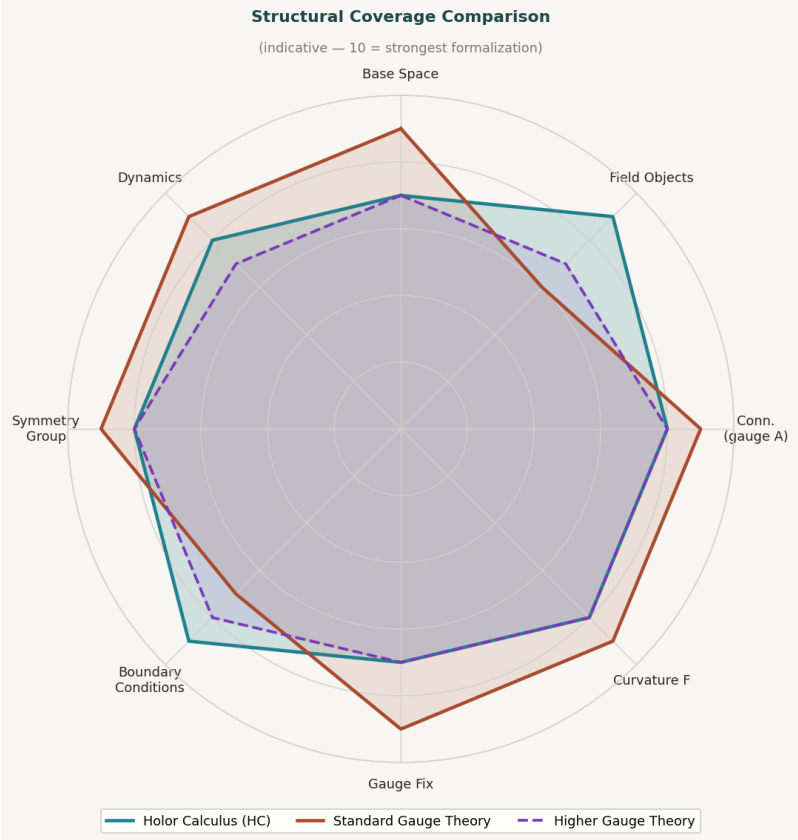
Figure 3 — Structural Coverage Radar



Reading the Radar Chart

Eight structural dimensions are rated (indicative scale 0–10) for each formalism:

- **Teal (HC):** Strong boundary conditions, chirality, ethics, holonomy
- **Red (Std. GT):** Strongest base space, connection, curvature, symmetry group
- **Purple (Higher GT):** Moderate everywhere; adds 2-forms and categorical structure

HC scores highest on Boundary Conditions (9) and Field Objects (9) due to its richer interior structure. Standard GT leads on Connection (9) and Gauge Fixing (9) due to its more mature formalism. All three share similar Dynamics scores.

Figure 3. Radar chart comparison. Scores are indicative assessments based on formalism richness, not value judgments. Each formalism is fit-for-purpose in its domain.

Figure 4 — Equation Lineage Map

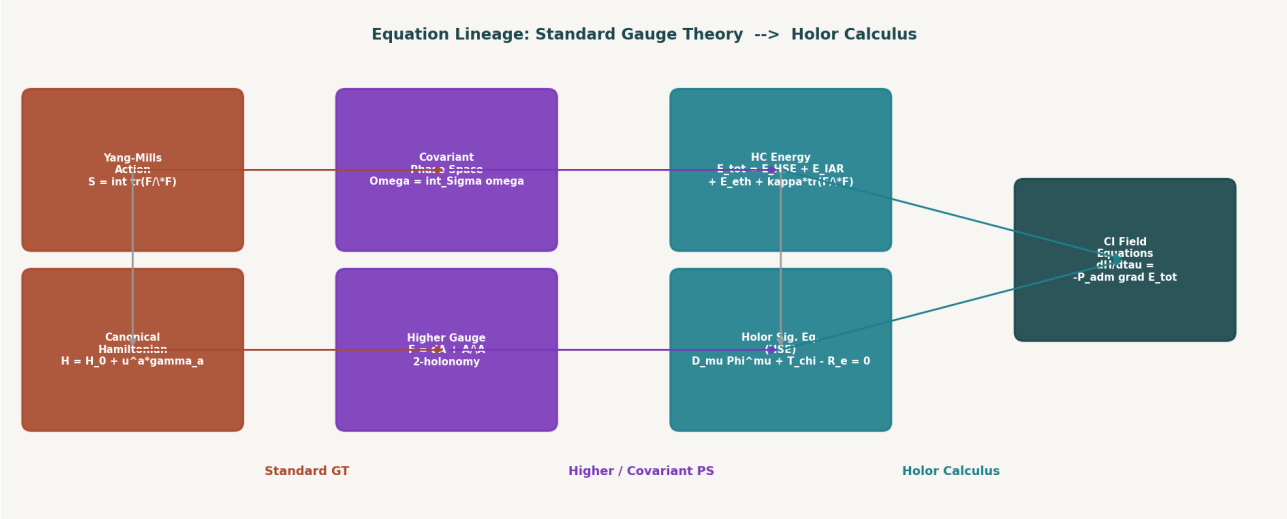


Figure 4. Lineage from standard gauge equations to Holor Calculus CI field equations. The Yang-Mills action and Canonical Hamiltonian feed into the Covariant Phase Space and Higher Gauge Theory; HC IV absorbs the Yang-Mills curvature term into E_tot^(IV), while the HSE provides an independent epistemic constraint, both flowing into the CI field evolution equation ∂_τH = -P_admgrad E_tot.

12 Advantages for Quantum Field Theory Applications

The following analysis assesses the potential contributions and advantages of the Holor Calculus framework for applications in quantum field theory, relative to existing gauge-theoretic approaches.

Domain	HC Advantage / Contribution	Standard GT Limitation Addressed	Maturity
Singularity Resolution	Conjugate throat structure (HC IX) reframes classical singularities as stable phase inversions — potentially avoiding renormalization divergences at the level of awareness geometry	QFT renormalization handles UV divergences procedurally; spacetime singularities require separate regularization (dim. reg., point splitting)	Theoretical (HC IX, 2026)
Boundary / Edge Modes	Chiral boundary operator ∂_χ (HC VII) with $\partial_\chi^2 = T_\chi^2 \neq 0$ provides a non-nilpotent boundary calculus — richer than standard de Rham ($\partial^2=0$)	Edge mode programs (2020–2025) still struggle with ambiguity in presymplectic potential θ; W/Y/Z freedoms require additional prescription	Formalized (HC VII, 2025)
Gauge-Invariant Regularization	P_adm projection + E_eth provide a geometry-based exclusion of pathological field configurations (Dracula attractor) — analogous to gauge-invariant UV cutoff through admissibility	Standard GT regulators (Pauli-Villars, zeta-function) break manifest gauge invariance or require restoration procedures	Conceptual (HC I–IV)
Non-Abelian Memory & Path Dependence	HC IV holonomy directly encodes path-dependent learning and order-sensitive gauge dynamics, with measurable empirical predictions (curriculum holonomy)	Non-Abelian holonomy in standard GT (Wilson loops) is primarily used for confinement; no direct connection to learning/memory systems	Formalized + Testable (HC IV, 2025)
Higher-Spin / Higher-Form Symmetries	HC's non-symmetric 50-signature operad (HC VII) provides a candidate Characteristica Universalis compatible with higher-spin gauge theories; SU(2) gauge morpheme σ_{30} embedded in CU	Higher-spin gauge theories (Vasiliev, HS-SUGRA) lack a unified symbolic framework relating all spin sectors — CU could provide this	Theoretical (HC VII, 2025)
Topological Field Theory	HC IV curvature term κtr(F/*F) connects to instanton number / Pontryagin class; chiral torsion T_χ parallels topological torsion in 3D Chern-Simons. HC bundle over awareness M is naturally a TQFT on interior spacetime	Standard TQFT (BF theory, Chern-Simons) lacks interior/epistemic content; HC adds ethical/chiral constraints as topological data	Heuristic (HC IV, HC VII)
Quantum Gravity Interface	HSE D_mu Phi^mu + T_χ - R_e = 0 structurally parallels Hollands-Wald identity in semiclassical gravity (arXiv:2510.19939); Berry curvature in CPSF has HC analogue in P_adm curvature of awareness manifold	Semiclassical gravity couples quantum matter via Berry curvature of purifications (2025 results); HC provides candidate epistemic analogue for interior degrees of freedom	Speculative (HC IX, 2026)

Table 6. QFT application advantages of Holor Calculus. Maturity column indicates current development stage. Most formalized advantages are in boundary conditions and non-Abelian holonomy; most speculative in quantum gravity interface. Sources: Butler (2025–2026), HC I–IX; François (2021); arXiv:2510.19939 (2025).

13 Open Problems and Research Directions

The following open problems emerge from the intersection of HC formalism and gauge theory. These are drawn from the HC Floating Hypothesis Space (FHS) and from structural gaps identified in the comparison.

ID	Problem	Description
OP-1	Presymplectic 2-Form for HC	Define $\omega_HC = \delta^2 E_tot$ as a 2-form on C_holor; prove it satisfies $d\omega_HC = 0$ on C_adm; compare with Lee-Wald presymplectic form. This would make HC a bona fide covariant phase space theory.
OP-2	Infinite-Dimensional Theory	HC I–IV work in finite-dimensional settings. Extend to infinite-dimensional holor field theories; prove Lyapunov convergence in Banach/Hilbert space setting.
OP-3	Gauge Group Identification	Identify the precise Lie group G for the non-Abelian connection A in HC IV. The chirality constraint $[g,\chi]=0$ suggests G is a chirality-preserving subgroup of a larger structure group. Classify all admissible G.
OP-4	Holonomy-Curriculum Experiment	Design and execute the empirical test of HC IV holonomy prediction: train Transformer models on permuted curricula of the Dracula task; measure persistent model differences as holonomy signatures.
OP-5	HC ↔ Covariant Phase Space	Formalize the relationship between E_tot and the presymplectic potential θ; identify whether the HC Noether charge Q_τ (for Spiral Time translations) has a standard gauge theory interpretation.
OP-6	Chiral Boundary Cohomology	HC VII's non-nilpotent ∂_χ ($\partial_\chi^2 = T_\chi^2 \neq 0$) defines a twisted cochain complex. Compute its cohomology; relate to torsion cohomology in Riemann–Cartan geometry.
OP-7	HC IX Singularity Resolution in QFT	Formalize the conjugate throat as a QFT regularization mechanism; compare with instanton tunneling and self-dual resolutions of gauge singularities.
OP-8	CU Operad ↔ Quantum Group	The 50-signature non-symmetric operad of HC VII: identify whether it admits a quantum group (Hopf algebra) deformation; relate σ_{30} (SU(2)) to standard loop quantum gravity representations.

Table 7. Open research problems. OP-1, OP-2, OP-5 are internal mathematical completions; OP-4 is empirically testable; OP-6, OP-8 connect HC to established mathematical structures. Source: HC Trilogy Outlook §3–4; Butler (2025).
